

# Chapter 1

## Library `abstract_completeness`

This text provides self contained formalized proofs of generalization of the completeness theorem of propositional and first order predicate calculus. It follows roughly <https://www.irif.fr/~krivine/article> although for the first order part the generalization rule we use is slightly different but is the one that can be found in most presentations of proof theory based on Hilbert systems.

The most striking aspect (in the opinion of the author) of the completeness theorem presented in the above article and here is the fact that the proof is intuitionistic and that we can extract programs from it. No additional axioms were used in the following coq file.

The plan we follow differs from the article. All the sets of formulas involved are assumed to be countable. First we prove the Lindenbaum lemma (which is actually the propositional completeness theorem) which asserts that for any formula  $F$ , any set of formulas which doesn't proves  $F$  using classical propositional calculus is contained in a maximal consistent set formulas which doesn't either proves  $F$  with these rules. When classical reasoning is available this theorem is obvious (the set is built by induction). A slight modification of this argument gives the intuitionistic case. Then we prove the completeness theorem for predicate calculus by first order logic, by extending the theory adding Henkin constants and then exploiting the propositional case on the theory obtained.

This method allows us to get models where witnesses are available for any universally quantified formula, which is a stronger form of the well known completeness theorem. Because of this, convenient applications are possible (e.g. easy proofs of skolemization).

Section `General_type_tools`.

The sets of formulas that we'll consider further in the text are of the form "Formula  $\rightarrow$  Type" rather than "Formula  $\rightarrow$  Prop" in order to allow full program extraction. The following tools are introduced in order to manipulate these objects.

Variable  $T$ :Type.

Section `Addition_of_a_new_item_to_a_type_valued_set`.

Variable  $P$ :  $T \rightarrow$  Type.

Variable  $n$ : $T$ .

Inductive `add_extra_item`:  $T \rightarrow$  Type:=

|aei\_base:  $\forall x:T, P\ x \rightarrow \text{add\_extra\_item}\ x$   
|aei\_new:  $\text{add\_extra\_item}\ n$ .

End Addition\_of\_a\_new\_item\_to\_a\_type\_valued\_set.

Section A\_special\_one\_step\_extension\_of\_a\_theory.

This paragraph is the only part where our text actually differs from usual proofs of the Lindenbaum's lemma, in order to accomodate with coq intuitionistic constraints. the rest of the text is tedious but probably straightforward if the reader knows how to prove completeness according to the route we've chosen i.e. Lindenbaum  $\rightarrow$  propositional case  $\rightarrow$

Henkin extension of a first order theory to exploit the propositional result. All these further part are usually already constructive.

Variable *base\_theory*: *Sentence*  $\rightarrow$  Type.

$\vdash p -o \text{gp\_specialize } q (\text{gp\_fresh\_variable } p q) \rightarrow$

$\vdash p -o q$ .

We explain what the objects above and especially “gp\_specialize” and “gp\_fresh\_variable” maps are intended to mean. A “general property” is simply a first order formula over a given signature. Let  $f$  be such a formula and  $t$  a term of the language. if  $f$  is “forall  $x$ ,  $g$ ” where  $g$  is another formula, then “gp\_specialize  $f t$ ” is nothing but  $g[x := t]$ , i.e. the the result of the capture-free substitution of  $x$  by  $t$  in  $g$ . In every other cases, gp\_specialize  $f t$  is  $f$  itself. This justifies the name “General\_Property” we’ve picked. If  $n \rightarrow v_n$  is the sequence of all the variables of the language (which will be assumed to be countable in the further

developments), then for every formulas  $a, b$ , “gp\_fresh\_variable  $a \ b$ ” is  $v\_m$  where  $m$  is the smallest integer such that  $v\_m$  has no free occurrences in  $a$  or in  $b$  (if you don’t know what that means: take “ $v\_m$  doesn’t appears in  $a$  or in  $b$ ”, this would give the same results at the end). `gp_theorem` is the proof system used and the properties “gp\_special\_case” and “gp\_generalization\_rule” are obvious (whether  $f$  and  $p$  are of the form “forall  $x \ g$ ” or not). The program offered is general enough so that hopefully it can be used in any reasonable implementation of first order logic. The only real constraint is that the set of formulas is countable.

No soundness theorem is provided (such a result would depend on how `gp_theorem` is actually defined), the user will have to provide one (which is usually easy).
